

Transactions in a batch

Tx1
(tid = 1, offset = 0)

Tx2
(tid = 2, offset = 1)
WAW-aborted

Tx3
(tid = 3, offset = 2)

Metadata stored in Table[key]

epoch = e
write_tid = 2
read_tid = 1

The table stores tids,
not abort-list indices.

WriterOffset

WriterOffset(2)
= 1

Single-node example:
offset = tid - 1

Abort list

slot 0
alive

slot 1
gen = e
aborted

slot 2
alive

One entry per transaction

During RAW checking, a transaction reads write_tid from metadata,
maps it to an abort-list entry, and ignores the writer if that
entry indicates a WAW abort in the current batch.
